

Homogenization as a microstructure probe tool a journey to the interior of cement paste

From concrete nanoscale to structure
celebrating Gilles CHANVILLARD's memory

Julien SANAHOJA (EDF lab) Luc DORMIEUX (ENPC)

5 july 2016

Introduction

Cementitious materials

- have time-dependent properties
- are multi-scale
- host multi-physics processes
- interact with their environment

Homogenization

- can bridge scales: physical processes → engineering behaviour
- can estimate microstructure influence on macroscopic properties

But cement paste microstructure

- is difficult to comprehensively observe in its multiscale nature
- may be too complex to be accurately modelled in full details

And cement paste macroscopic properties

- are easy to measure
- are of direct interest for engineers

General strategy

- “focus on first order effects”
start with a simplified morphological model
- “equations have to be nice and efficient”
use mean-field homogenization
- “be demanding on model validation”
compare predictions to experimental measurements
- iterate this trial-and-error process
 - comparison OK \Rightarrow get other experimental data to compare
 - comparison KO \Rightarrow go back to morphological model and improve it

Outline

- 1 Hydrates growing around cement grains
 - Basic morphological model based on MRP
 - Prediction of setting: issues
 - Setting issues: mitigation
- 2 Introduction of inner/outer hydrates
 - Outer products precipitating as spherical clusters
 - Intermission: does shape matter?
 - Introduction of C-S-H bricks and platelets
- 3 Further comparisons and extensions
 - Late age: more experimental data
 - Early age: more experimental data and model improvement
 - Towards basic creep: an overview

Hydrates growing around cement grains

Simplified view of cement paste

3 phases: **anhydrous**, **hydrates**, **capillary porosity**

A common morphological model

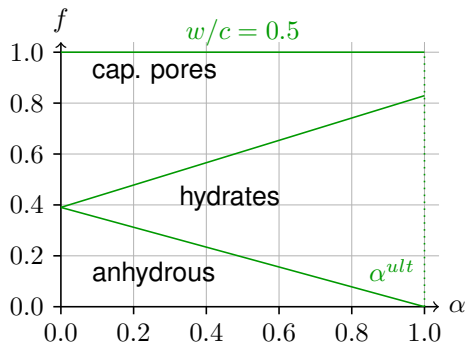

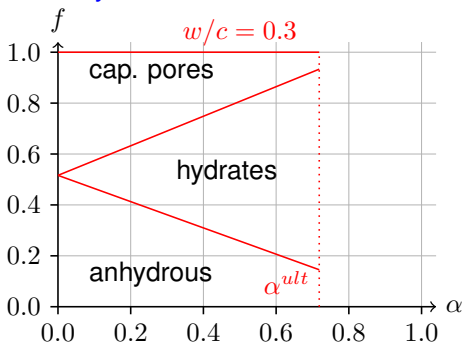

Generalized self-consistent scheme

Input data: phases volume fractions and elasticity

Hydration: Powers model [Powers et al., JACI 43, 1946]

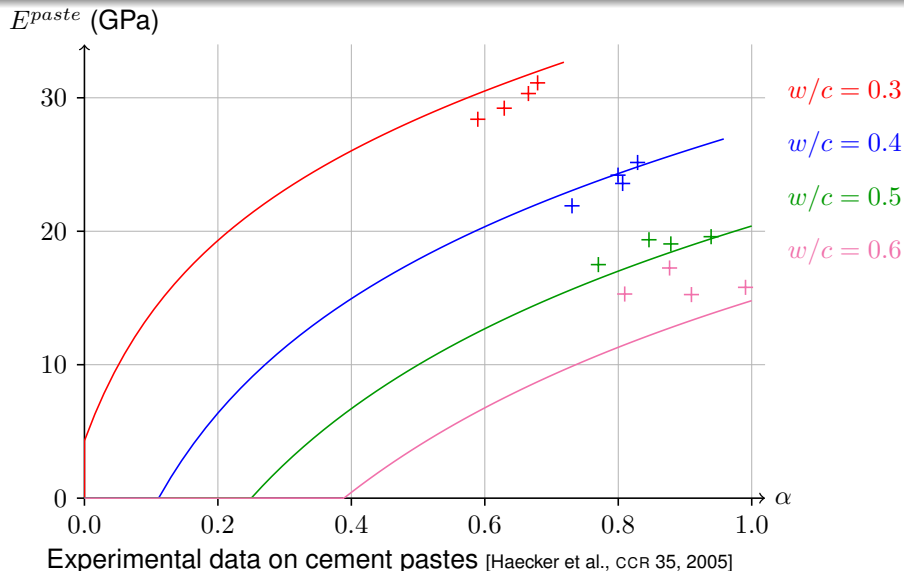

Elastic properties

	E (GPa)	ν	source
anh.	135	0.3	nano-indentation ¹
hyd.	31	0.24	nano-indentation ²

¹[Velez et al., CCR 31, 2001], ²[Velez et al., Kurdowski symp., 2001]

Effective stiffness from MRP-based model

Experimental estimation of setting degree of hydration

Experimental data: linear regression [Torrenti et al., Mas 38, 2005],
 strength data [Byfors, PhD, 1980] and [Taplin, AJAS 10, 1959]

An attempt to interpret SCS implicit morphology

Interpenetrating spheres on
primitive cubic lattice
FEM computations $\Rightarrow k^{eff}$

$$\varphi = 0.6$$

$$\varphi = 0.3$$

Self-consistent scheme

$$\Rightarrow \mathbb{C}^{eff}$$

Self-consistent scheme VS spheres on cubic lattice

Towards a multiscale description

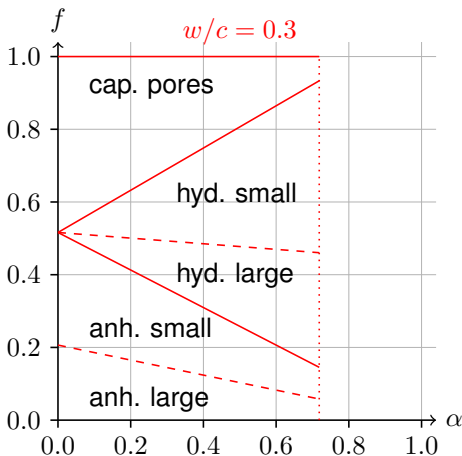

Current morphological model \approx monodisperse distribution of spheres
 \Rightarrow instantaneous setting for $w/c < 0.32$

To mitigate this issue: **multiscale** description of cement grains
starting with two separated scales

Phases volume fractions

Hydration: Powers + hydration rate size-independent (simplification)
 small particles: 60 %

Effective stiffness from 2-scales MRP-based model

Outline

- 1 Hydrates growing around cement grains
 - Basic morphological model based on MRP
 - Prediction of setting: issues
 - Setting issues: mitigation
- 2 Introduction of inner/outer hydrates
 - Outer products precipitating as spherical clusters
 - Intermission: does shape matter?
 - Introduction of C-S-H bricks and platelets
- 3 Further comparisons and extensions
 - Late age: more experimental data
 - Early age: more experimental data and model improvement
 - Towards basic creep: an overview

Setting controlled by outer hydrates

Completely avoid instantaneous setting

consider cement grains as inclusions in a matrix

Introduction of **high/low** density hydrates as **inner/outer** products

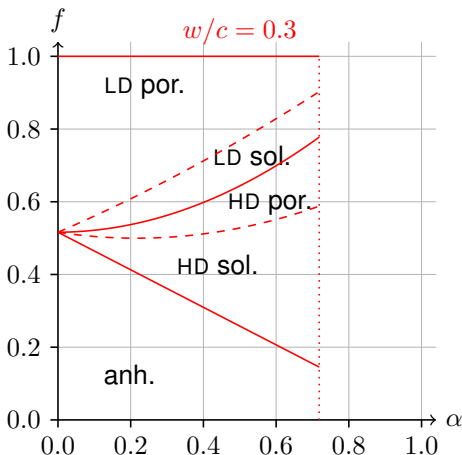

Setting of outer \Rightarrow setting of paste

Hydration with HD and LD hydrates

Hydration: Powers model

+ repartition HD / LD hydrates [Tennis et al., CCR 30, 2000]

+ $\varphi_{hd} = 0.3$ (from 0.28 [Powers] to 0.30, 0.35 [Tennis et al., CCR 30, 2000])

Effective stiffness from inner/outer model

Is the spherical shape relevant for hydrate solids?

AFM observation of a C_3S crystal covered by a lime-saturated droplet

[Garrault-Gauffinet, PhD, 1998]

Small particles of C-S-H
anisotropic shape

- parallel to the grain surface
60 nm by 30 nm
- thickness: 5 nm

⇒ elementary bricks of C-S-H
aspect ratio $r_s = 5/\sqrt{30 * 60} \approx 0.12$

Question of the morphology of C-S-H still widely opened
we chose a representation based upon these elementary bricks

The gypsum “interlude”

Gypsum: elongated crystals

Experimental data on gypsum [Meille, PhD, 2001], [Colak, ML 60, 2006], [Ali et al., JMS 10, 1975], [Phani, ACSb 65, 1986], [Tazawa, ACBM 7, 1998]

An attempt to take into account elongated particles

elongated particles, random orientation

Parallelepipeds (21*3*3 voxels)
randomly put into a cube
FEM computations

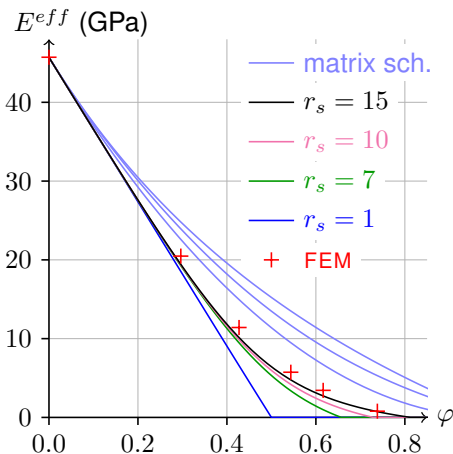

[Meille, PhD, 2001]

Self-consistent scheme
solid inhomogeneity = prolate spheroid
+ isotropic orientation distribution

Scs with prolate-shaped solid VS FEM

Critical porosity $\phi^c = 1 - f_s^c$ depends on prolate aspect-ratio r_s

FEM results [Meille, PhD, 2001]

SCS critical solid volume fraction VS geometry

Geometrical percolation of spheroids [Garboczi et al., PRE 52, 1995]

Oblate-shaped hydrate solids

high density
hydrates
(inner)
bricks
+ gel pores

low density
hydrates
(outer)

“platelets”
+ gel and capillary
pores

Input data: elastic and morphological parameters

	E (GPa)	ν	φ	a.r.	source
anh.	135	0.3			nano-indentation ¹
hyd. HD	31	0.24	0.3	0.12	nano-indentation ² , porosity ³ , AFM ⁴
hyd. LD	evol.	evol.	evol.	0.033	self-consistent scheme, hydration model, setting
hyd. solids	71.6	0.27			reverse analysis hyd. HD

LD aspect-ratio: fit on setting results

Rem: atomic scale modelling [Pellenq et al., CCR 38, 2008]

tobermorite C/S=0.83

Young's modulus: 54 (\perp sheets); 68, 72 (\parallel sheets) GPa

¹[Velez et al., CCR 31, 2001], ²[Velez et al., Kurdowski symp., 2001], ³[Tennis et al., CCR 30, 2000],

⁴[Garrault-Gauffinet, PhD, 1998]

Effective stiffness from inner/outer with bricks/platelets

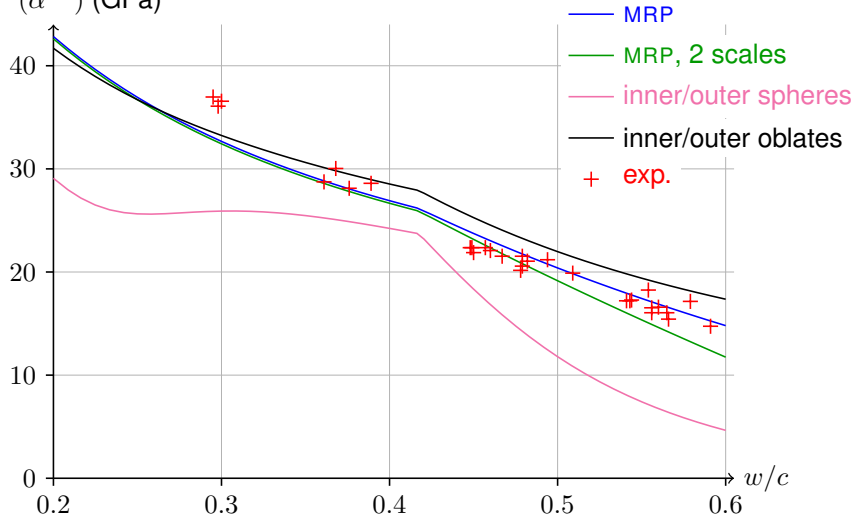

Outline

- 1 Hydrates growing around cement grains
 - Basic morphological model based on MRP
 - Prediction of setting: issues
 - Setting issues: mitigation
- 2 Introduction of inner/outer hydrates
 - Outer products precipitating as spherical clusters
 - Intermission: does shape matter?
 - Introduction of C-S-H bricks and platelets
- 3 Further comparisons and extensions
 - Late age: more experimental data
 - Early age: more experimental data and model improvement
 - Towards basic creep: an overview

Mature pastes: $\alpha = \alpha^{ult}$

$E^{paste}(\alpha^{ult})$ (GPa)

Experimental data [Helmuth et al., Symp. Struct. of Portl. C.P. and Concr., 1966]

Hydration degree at setting

Experimental data [Torrenti et al., MAS 38, 2005]

Setting: more insights at early age

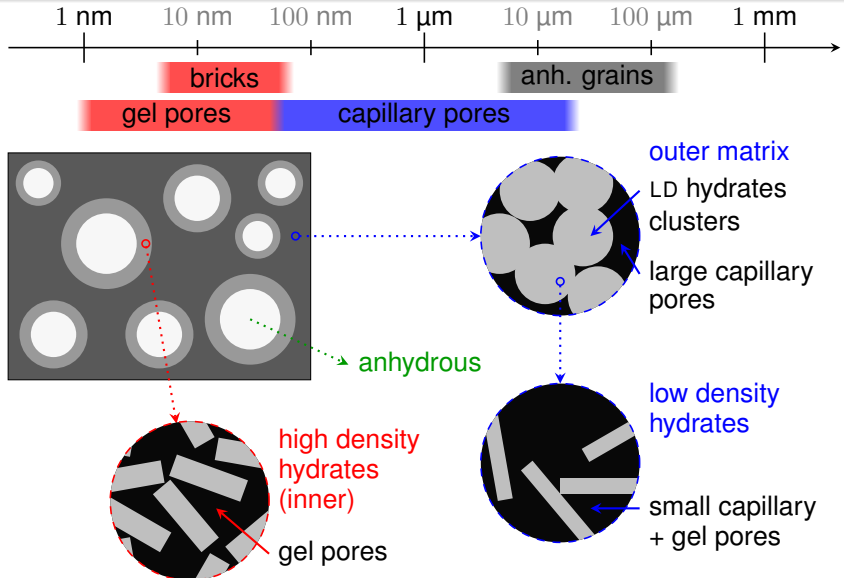

E_{us}^{paste} (GPa)

Continuous monitoring of stiffness, from fluid state?

- **Ultra-sonic meas.** [Boumiz et al., 2nd Rilem workshop on hydration and setting, 1997]
- **EMM-ARM technique** [Azenha et al., CCR 40, 2010]

Scale separation in outer hydrates

Effective stiffness from 2-scales outer

Converting elastic model to basic creep model

Only one extra parameter: Maxwell sliding characteristic time τ

Creep of cement paste VS experimental data

Assumption: frozen microstructure ($\alpha = \alpha^{ult}$)

⇒ Laplace-Carson transform: non ageing viscoelasticity → elasticity

$\varepsilon(t) - \varepsilon_0$ ($10^{-6}/\text{MPa}$) - - - - LD pores: monoscale ($\tau = 0.56$ d)

— LD pores: small/large ($\tau = 0.82$ d)

$w/c = 0.5$

$w/c = 0.38$

$w/c = 0.28$

Experimental data on cement pastes (28 d) [Le Roy, PhD, 1995]

Thanks Gilles

A morphological model of cement paste

- simplified (hydrates not detailed)
- efficient (mean field homogenization)
- validated (at both early and late ages)
- not just about elasticity prediction (can be extended to creep)

Many sources of improvement and prospects

- morphology: differentiate mineral phases + upscale to concrete
- improve chemical modelling
(hydration, degradation mechanisms, ...)
- more experimental comparisons
- investigate other mechanical properties
(creep, strength, damage, ...)
- investigate transport properties

Paper co-authored with Gilles on cement paste
